In this article the synthesis of Fe₃O₄@MCM-41@NH-2,6-pydc as good adsorbent with potential of many applications, by coprecipitation method, was reported. For this purpose, Fe₃O₄ was synthesized, then protected with MCM-41 as a shell. Afterward, Fe₃O₄@MCM-41 functionalized by 2,6-pyridine dicarboxylic acid (pydc) after modifying by 3-aminopropyl trimethoxysilane (APTMS). This adsorbent characterized by means of X-ray diffraction (XRD), Fourier transform infrared spectroscopy (FT-IR), energy dispersive X-ray (EDX), scanning electron microscope (SEM), Brunauer–Emmett–Teller (BET), differential thermal analysis (DTA), thermogravimetric analyses (TGA) and derivative thermogravimetric (DTG). The vibrating sample magnetometer (VSM) has been used to investigate its magnetic properties.

Introduction

Magnetic nanoparticles and their functionalized, attract plenty attention through their markable usages in different field such as biotechnology [1], metal ion extraction [2], carriers for targeted drug delivery [3], optical imaging [4], electronic [5], magneto resistance [6] and catalyst [7]. In which magnetic nanoparticles are present, specially for Fe₃O₄ nanoparticles have individual, features including superparamagnetism, high surface area, large surface-to-volume ratio, facile separation by external magnetic fields [3, 8-10]. Also due to their good biocompatibility and low toxicity, Fe₃O₄ nanoparticles are the most preferable [11-14]. However, Fe₃O₄ nanoparticles are inclined to aggregate, oxidize and decompose, and thus it is essential to protect their surfaces [15]. The purpose of shell coating of nude magnetic nanoparticles in core–shell structure is insulating the magnetic core versus the environment [16].

One important clansman of the M41S mesoporous molecular sieve family is mesoporous MCM-41, with a hexagonal arrangement of uniform channels of 15–100 Å diameter. The MCM-41 synthesis process begins by utilizes quaternary alkylammonium salts like cetyltrimethylammonium bromide (CTAB) in an aqueous solution under basic conditions. The ionic surfactant form spherical micelles that form template by forming a liquid crystalline phase [17]. The hydrolysis and condensation of silica precursors, as an example tetraethylorthosilicate (TEOS) forms a solid silicate mesostructure around the template because of electrostatic interactions between the negatively charged silica species and head groups of the surfactant, or by hydrogen bonding interactions. Ultimately the template is removed by calcination after formation of the silicate mesostructure [18].

Due to its very high surface area (up to 1000 m²/g), its narrow size pore distribution and thermal stability (up to 800°C) [19,20], it will be an assorted support material for Fe₃O₄ nanoparticles.

The surface modification of magnetic nanoparticles could improve selectivity, dispersity and biocompatibility, that could appreciably simplify its beneficiary [21]. Because of hydrophilic surfaces of silica-coated magnetic nanoparticles, this shell alone cannot stabilize the nanoparticles in a specific qualification but it could be easily modified with other functional groups [22].

This material has been prepared by precipitation [23], co-precipitation [24] and hydrothermal [25] methods. Amid these methods, chemical co-precipitation may be the most encouraging, due to its facility and efficiency [16].

Using differing polymers with different functional groups for functionalizing magnetic Fe₃O₄ nanoparticles and MCM-41 mesoporous can augmented its adsorption capacity and selectivity [26]. So the cited nanoparticles and mesoporous was used for many purposes such as solid phase extraction [27], removal of ions [28], delivery of biomolecules [29] and etc.

By functionalizing of magnetic Fe₃O₄ nanoparticles or MCM-41 mesoporous, they could be used to adsorb, preconcentrate and extract the cationic species analogous protonated form of drug and amines, basic and cationic dyes, amino acids and metal ions. So because of the good properties of carboxylate positions for interactions with organic and inorganic cations, it is suitable for functionalizing. Bygone research by Shokrollahi and colleagues represent pleasant interactions between 2,6-pyridine dicarboxylic acid (pydc) and different bases like piperazines [30] amino pyridines [31] and acridines [32]. Based on the previous researches, it is anticipated that
nanoparticles functionalized by pydc could be utilized as a proper surface for the adsorption, extraction and preconcentration of organic and inorganic compounds. According our previous study [33], Fe₃O₄@SiO₂-NH₂-2.6 pydc was synthesized as a good adsorbent in easy separation, but the adsorption capacity of it can be improved by coating with MCM-41.

The purpose of this study is, using co-precipitation method for synthesis Fe₃O₄ and afterward form an outer shell by coating MCM-41. Then the surface of these nanoparticles is loading through the grafting by APTMS and ultimately functionalized by pydc.

**Experimental**

**Materials**

Ferrous chloride tetrahydrate (FeCl₂·4H₂O), ferric chloride hexahydrate (FeCl₃·6H₂O), cetyltrimethyl ammonium bromide (CTAB), ammonium hydroxide (25%, w/w), tetraethyl orthosilicate (TEOS), (3-aminopropyl) trimethoxysilane (APTMS), Toluene (C₆H₅), 2,6-pyridine dicarboxylic acid (2,6-pydc), ethanol (C₂H₅OH, 99.7%), dichloromethane (CH₂Cl₂) and triethylamine (N(CH₃)₃), methyl green, mallachite green, and phenylalanine were purchased from Merck chemical company (Darmstadt, Germany). Thiocol chloride (SOCl₂) was purchased from Sigma-Aldrich Company (St. Louis, Germany).

**Apparatus**

XRD spectra were taken on a Philips XPERT MPD X-ray diffractometer with Cu-Kα radiation (λ = 1.5406 Å) and scanning mode from 0° (20) to 80° (20). IR spectra were obtained in the range 400 to 4000 cm⁻¹ using KBr pellets on a Jasco 460 FT-IR spectrometer. The magnetic properties of Fe₃O₄ and Fe₃O₄@MCM-41-NH₂-2,6pydc were measured with VSM (MDKB, Daghigh Meghnati kavir Co., Iran). Scanning Electron Microscope model Sigma VP from ZEISS Company was applied for the morphological structure of nanoparticle. The specific surface, the pore size distribution, and the total pore volume were determined from N₂ adsorption–desorption isotherms obtained by using a Micrometrics ASAP 2020. The TGA and DTA were done on a Perkin Elmer Pyres diamond TG/DTA instrument in N₂ atmosphere at a heating rate of 20°C min⁻¹ from 28 to 887°C. An ultrasonic bath with heating system (Tecnico-GAZ SPA Ultrasonic System, Italy) at 40 kHz of frequency and 130 W of power.

**Synthesis of Fe₃O₄**

Co-precipitation technique has been used to prepare magnetic Fe₃O₄ nanoparticles. FeCl₂·4H₂O (4.0g) and FeCl₃·6H₂O (10.8g) were dissolved in 100 mL double distilled water under nitrogen purging. Ammonia (50.0 mL, 25%) was added into the solution dropwise to adjust the pH value to approximately 9.0 and the brown color solution turned out to black. After vigorously stirred for 30 min, the temperature should be 70°C. The precipitate was collect by powerful external magnet and was washed with double distilled water and ethanol for several times. The resulting black powder was dried in an oven at 40°C.

**Synthesis of Fe₃O₄@MCM-41**

For the preparation of Fe₃O₄ at the mobile composition of matter No. 41 (MCM-41), 0.3g of Fe₃O₄ was dispersed in absolute ethanol (210mL) under sonication for 30 min and CTAB (1.5g) was stirred in 180mL of deionized water for 30 min at room temperature. Two above solutions were mixed followed by an addition dropwise of tetraethylorthosilicate (TEOS; 3mL), ammonia (15 mL, 25%) and stirred at room temperature for 24 h. The obtained Fe₃O₄ nanoparticles coated with mesoporous silica were washed with ethanol (total 40mL) and acetone (total 30mL) several times, separated magnetically and dried at 50°C. The dried sample was finally calcinated at 500°C for 9h for the extraction of template CTAB.

**Synthesis of Fe₃O₄@MCM-41-NH₂**

For surface modification of the Fe₃O₄@MCM-41 with APTMS, APTMS (1.0mL) and Fe₃O₄@MCM-41 (about 1.0g) were added in toluene (20mL). The mixture was permitted to react by refluxing at 110 °C for 24 h. After this time, the production Fe₃O₄@MCM-41-NH₂ were separated magnetically, and washed with toluene (20mL) and ethanol (20mL). The Fe₃O₄@MCM-41-NH₂ was dried in an oven at 50°C.

**Synthesis of Fe₃O₄@MCM-41-NH₂-2,6-pydc**

The solution of 2,6-pyridine dicarboxylic acid (0.5g) in SOCl₂ (8.72 mL) was heated to reflux (70°C) and kept at reflux for 18 h. After the remaining SOCl₂, was evaporated of system, Fe₃O₄@MCM-41-NH₂ (0.8g), triethylamine (43.63µL) and CH₂Cl₂ (8.72mL) were added to a beaker respectively, then the reaction mixture was stirred at room temperature for 6 h. The product (Fe₃O₄@MCM-41-NH₂-2,6-pydc) was filtered and washed with ethanol then was dried in an oven at 50°C.
**Characterizations**

X-ray diffraction (XRD), Fourier transform infrared spectroscopy (FT-IR), scanning electron microscope (SEM), energy dispersive X-ray (EDX), vibrating sample magnetometer (VSM), Brunauer–Emmett–Teller (BET), thermogravimetric analysis (TGA), derivative thermogravimetric (DTG) and differential thermal analysis (DTA) were used to check out and distinction of synthesized magnetic nanoparticles.

**Results and discussion**

**XRD analysis**

To recognition the crystalline structure of the synthesized nanoparticles, it was analyzed by X-ray diffraction from 0° (20) to 80° (20) ([Fig. 2](image)). [Fig. 2a](image) shows six characteristic peaks indicated a crystallized structure at 2θ of 30.52°, 35.81°, 43.50°, 53.87°, 57.61° and 63.18° which was dedicated to the Fe₃O₄ crystal plan (200), (311), (400), (422), (511) and (440), respectively. These results were compared to the reference No 96-900-5842, confirming the highly spinal structure. [Fig. 2b](image) shows the XRD spectrum of Fe₃O₄@MCM-41-NH2-2,6pydc and it’s similar to [Fig. 2a](image) except a broad diffusion peak at 2θ of 19.54° related to the SiO₂ amorphous phase (Ref. No 96-210-1989). These results revealed that the initial crystallographic structure of Fe₃O₄ was preserved perfectly during the surface modification process.

**FT-IR analysis**

As seen in [Fig. 3](image) the functional groups in the synthesized nanoparticles were recognized by FT-IR analysis. The presence of vibration band at 586 cm⁻¹ demonstrates the existence of Fe₃O₄ and it is observed in all three spectra. The vibration band that observed at 1064 cm⁻¹ ([Fig. 3b](image) and [Fig. 3c](image)) refers to SiO₂ and shows that Fe₃O₄ protected with MCM-41. Also, the acidic OH peak appearance at 3409 cm⁻¹. The N-H stretching vibration band related to N-H group of 3-aminopropyl can be intended at 3300-3400 cm⁻¹. But it is noteworthy the apparition of a broad peak instead of a sharp peak, is regarding to the attendance of unlimited OH groups on the surface. The presence of pyridine ring can be confirmed by the peak at 1454-1564 cm⁻¹ that refers to C=C and C=N ([Fig. 3c](image)). The absorption band that assigned to C=O is demonstrated at 1621 cm⁻¹. Finally, we conclude that Fe₃O₄@MCM-41-2,6 pydc was successfully synthesized.

**SEM analysis**

The scanning electron microscopy (SEM) images of the Fe₃O₄@MCM-41-NH₂-2,6-pydc ([Fig. 4](image)) in two magnification showed micro size of smooth spherical particles.

EDX analysis

The EDX spectrum of Fe₃O₄@MCM-41-NH-2,6pydc (Fig. 5), showed an elemental composition of Fe, Si, O, C and N for the material.

VSM analysis

The magnetic parameters of the Fe₃O₄ and Fe₃O₄@MCM-41-NH-2,6-pydc were measured at room temperature by vibrating sample magnetometer (VSM) analysis (Error! Reference source not found.). Saturated magnetic property (Ms), amount of residual or magnetic stability (Mr) and negative or reversing force (Hc), are magnetic parameters that have been obtained from the curves and shown in Table 1. As seen in the curves of MS for different materials were weakened, indicating that Fe₃O₄ nanoparticles were coated by the non-magnetic material. So the decrease in magnetic property shows successful modification of Fe₃O₄ nanoparticles with MCM-41 mesoporous and the Ms for Fe₃O₄ ranges from 57.47 to 7.80 emu/g diminished. Consequently, the plot shows that the Fe₃O₄@MCM-41-NH-2,6-pydc exhibit a typical super paramagnetic behavior due to their small magnetic stability.

BET analysis

Nitrogen adsorption/desorption isotherm and the corresponding pore size distribution of Fe₃O₄@MCM-41-NH-2,6pydc are shown in Fig. 7 Fig. 8. Isotherm curves in Fig. 7 can be attributed to type IV according to the IUPAC classification, and the curves confirmed that after the modification, the samples maintained their mesoporous structures [34]. The corresponding pore size distribution of the sample (Fig. 8) showed that the pore size was between 1–100 nm. The surface area, pore volume and pore size are shown in Table 2. These result in comparing the reports about Fe₃O₄@MCM-41, has confirmed that the functionalizing with 2,6-pydc decreased the BET surface area, pore volume and pore size. However the purposed adsorbent has better properties than the similar cases in reports [35].

Thermal stability analysis

TGA, DTG and DTA was used for appraising the thermal stability of synthesized Fe₃O₄@MCM-41-NH -2,6-pydc. The TGA curves (W vs. T and W% vs. T scales) of Fe₃O₄ nanoparticles and Fe₃O₄@MCM-41-NH-pydc are shown in Fig. 9 and Fig. 10 respectively. According to the graphs, there are three decomposition peaks that the first one in the range 28-147°C alluded to evaporation of solvent that adsorbed on the surface of nanoparticles. Two other weight loss in the range of 147-302 and 302-678°C can be alluded to decomposition of pydc and APTMS. Also these changes are shown distinctly in the DTG. DTA [36], approved these reasoning. So there are peaks in DTA in places that lose weight in DTG were happened. Albeit heat events that are regarding to change in energy can be detectable with DTA, the other heat events that are related to change in mass cannot be detectable.

Ability of Fe₃O₄@MCM-41-NH -2,6-pydc as an adsorbent

The ability of the cited mesoporous was tested by using as an adsorbent for removal or preconcentration of some dyes and amino acids such as methyl green, malachite green and phenylalanine. It seems that this mesoporous has good absorption capacity and it is a good adsorbent for removing of methyl green and malachite green. Also it is an efficient adsorbent for preconcentration and extraction of these dyes and phenylalanine amino acid in low level concentrations.

Conclusions

Achievements of this research, is synthesis of magnetic Fe₃O₄ nanoparticle and increasing of its stability with MCM-41 mesoporous. Also using APTMS as a modifier can improve dispersity and biocompatibility. The functionalizing of purpose nanoparticles with 2,6-pydc can raise the selectivity. Resulting is, formation Fe₃O₄@MCM-41-2,6-pydc as a benefit and optional adsorbent for purposes such as removal, separation and extraction of organic and inorganic species. XRD, FT-IR, EDX and thermal analyses confirm this synthesis and VSM curves shows, though the modifier decreased magnetism, still it has magnetic properties. Fe₃O₄@MCM-41-2,6-pydc is a good adsorbent due to easy separation and high capacity. Also the potency to interact with cationic species can be facilitated by functionalizing with carboxylate groups.

Although the new synthesized adsorbent have less magnetic feature toward Fe₃O₄@SiO₂-NH-pydc [33] but because of existence MCM-41 in structure it has more surface area. So it is an adsorbent that competitive with Fe₃O₄@SiO₂-NH-pydc and functionalized MCM-41 and in addition appropriate surface area, it is easily separated from analyte. If we take look at some similar synthesis of other researchers we will come to this conclusion that our syntheses have desirable properties [35,37] and functionalized by 2,6-pydc prepares it for our intended purposes.

The adsorption capacity of the Fe₃O₄@MCM-41-2,6pydc examined by removing or preconcentration of some dyes and amino acids including methyl green, malachite green and phenylalanine. The results show the excellent adsorption capacity compare to similar nanoparticles [38].
